A METHOD FOR CALCULATION OF MORSE POTENTIAL FOR FCC, BCC, HCP CRYSTALS APPLIED TO DEBYE-WALLER FACTOR AND EQUATION OF STATE

NGUYEN VAN HUNG

Dept. of Physics, College of Natural Sciences
Hanoi National University

Abstract. Analytical expressions for the Morse potential parameters for fcc, bcc and hcp crystals have been developed. They contain the energy of sublimation, the compressibility and the lattice constant. Numerical results for Cu (fcc), W (bcc) and Zn (hcp) agree well with the measured values. Debye-Waller factors in X-ray absorption fine structure (XAFS) and equation of state computed using the obtained Morse potential parameters agree well with the experimental results.

I. INTRODUCTION

Interatomic anharmonic potential, especially Morse potential, has been studied widely [1-12]. The parameters of this potential can be extracted from the XAFS [11, 12]. They are also used to calculate thermodynamic parameters included in these spectra [4-10]. This potential is successfully applied to calculating the quantities involving atomic interaction, especially, the anharmonic effects contained in XAFS [5-10] which influence on the physical information taken from these spectra. They are also contained in the expressions of equation of state. Therefore, calculation of the Morse potential is very actually desired, especially in XAFS theory.

The purpose of this work is to develop a method for calculating the Morse potential parameters of fcc, bcc and hcp crystals. Analytical expressions for the parameters of this potential have been derived. They contain the energy of sublimation, the compressibility and the lattice constant which are known already, for example see [13, 21]. The obtained results are applied to Debye-Waller factors contained in the XAFS spectra [4-10,14] and to equation of state. Numerical calculations have been carried out for Cu (fcc), W (bcc) and Zn (hcp). The calculated Morse potential parameters agree well with the measured values [11, 12, 15] and with the other theory results [1]. Debye-Waller factors and equation of state computed using the obtained Morse potential parameters are found to be in good agreement with experiment [17, 18-21].

II. PROCEDURE FOR CALCULATION OF MORSE POTENTIAL

The potential energy $\varphi (r_{ij})$ of two atoms $i$ and $j$ separated by a distance $r_{ij}$ is given in terms of the Morse function by

$$\varphi (r_{ij}) = D \left\{ e^{-2\alpha (r_{ij} - r_o)} - 2 e^{-\alpha (r_{ij} - r_o)} \right\},$$

(1)
where \( \alpha, D \) are constants with dimensions of reciprocal distance and energy, respectively; \( r_o \) is the equilibrium distance of the two atoms. Since \( \varphi (r_o) = -D \), \( D \) is the dissociation energy.

In order to obtain the potential energy of the whole crystal whose atoms are at rest, it is necessary to sum Eq. (1) over the entire crystal. This is most easily done by choosing one atom in the lattice as an origin, calculating its interaction with all the others in the crystal, and then multiplying by \( N/2 \), where \( N \) is the total atomic number in the crystal. Thus the total energy \( \Phi \) is given by

\[
\Phi = \frac{1}{2} N D \sum_j \left\{ e^{-2\alpha(r_j-r_o)} - 2e^{-\alpha(r_j-r_o)} \right\}.
\]

(2)

Here \( r_j \) is the distance from the origin to the \( j \)th atom. It is convenient to define the following quantities

\[
L = \frac{1}{2} N D; \quad \beta = e^{\alpha r_o}; \quad r_j = \left[ m_j^2 + n_j^2 + l_j^2 \right]^{1/2} = M_j a,
\]

(3)

where \( m_j, n_j, l_j \) are position coordinates of any atom in the lattice. Using Eqs. (3) for Eq. (2), the energy can be rewritten as

\[
\Phi(a) = L \beta^2 \sum_j e^{-2\alpha M_j} - 2L \beta \sum_j e^{-\alpha M_j}.
\]

(4)

The first and second derivatives of the energy of Eq. (4) with respect to \( a \) are given by

\[
\frac{d\Phi}{da} = -2\alpha L \beta^2 \sum_j M_j e^{-2\alpha M_j} + 2L \beta \alpha \sum_j M_j e^{-\alpha M_j},
\]

(5)

\[
\frac{d^2\Phi}{da^2} = 4\alpha^2 L \beta^2 \sum_j M_j^2 e^{-2\alpha M_j} - 2\alpha^2 L \beta \sum_j M_j^2 e^{-\alpha M_j}.
\]

(6)

At absolute zero \( T = 0 \), \( a_o \) is value of \( a \) for which the lattice is in equilibrium, then \( \Phi(a_o) \) gives the energy of cohesion, \( [d\Phi/da]_{a_o} = 0 \), and \( [d^2\Phi/da^2]_{a_o} \) is related to the compressibility [1]. That is,

\[
\Phi(a_o) = U_0(a_o),
\]

(7)

where \( U_0(a_0) \) is the energy of sublimation at zero pressure and temperature, i.e.,

\[
\left( \frac{d\Phi}{da} \right)_{a_o} = 0,
\]

(8)

and the compressibility is given by [1]

\[
\frac{1}{K_00} = V_0 \left( \frac{d^2U_0}{dV^2} \right)_{a_o} = V_0 \left( \frac{d^2\Phi}{dV^2} \right)_{a_o},
\]

(9)
where $V_0$ is volume at $T = 0$, and $K_{00}$ is compressibility at zero temperature and pressure. The volume per atom $N/V$ is related to the lattice constant $a$ by

$$ V/N = ca^3. \quad (10) $$

Substituting Eq. (10) in Eq. (9) the compressibility is expressed by

$$ \frac{1}{K_{00}} = \frac{1}{9cNa_0} \left( \frac{d^2\Phi}{da^2} \right)_{a=a_0}. \quad (11) $$

Using Eq. (5) to solve Eq. (8) we obtain

$$ \beta = \sum_j M_j e^{-\alpha aM_j} / \sum_j M_j e^{-2\alpha aM_j}. \quad (12) $$

From Eqs. (4), (6), (7) and (11) we derive the relation

$$ \frac{\beta \sum_j e^{-2\alpha aM_j} - 2 \sum_j e^{-\alpha aM_j}}{4\alpha^2 \beta \sum_j M_j^2 e^{-2\alpha aM_j} - 2\alpha^2 \sum_j M_j^2 e^{-\alpha aM_j}} = \frac{U_0 K_{00}}{9cNa_0}. \quad (13) $$

Solving the system of Eqs. (12), (13) we obtain $\alpha, \beta$. Substituting the obtained results into the second of Eqs. (3) we derive $r_0$. Using the obtained $\alpha, \beta$ and Eq. (4) to solve Eq. (7) we obtain $L$. From this $L$ and the first of Eqs. (3) we obtain $D$. The obtained Morse potential parameters $D, \alpha$ depend on the compressibility $K_{00}$, the energy of sublimation $U_0$ and the lattice constant $a$. These values of about all crystals are known already [13].

### III. APPLICATION TO CALCULATION OF PHYSICAL QUANTITIES

1. **Debye-Waller factors in XAFS theory**

   The expression for the K-edge XAFS function [10]

   $$ \chi(k, T) \sim e^{-2k\sigma^2(T)} \quad (14) $$

   is proportional to the Debye-Waller factor $e^{-2k^2 \sigma^2}$ defined by the mean square relative displacement (MSRD) $\sigma^2$ in temperature $T$ dependence, $k$ is wave number of the photo-electron. The expression for the MSRD in XAFS theory is derived based on the correlated Einstein model [9] which is considered, at present, as “the best theoretical framework with which the experimentalist can relate force constants to temperature dependent XAFS” [15]. According to this theory the effective interaction Einstein potential of the system is given by

   $$ V_{eff}(x) = \frac{1}{2} k_{eff} x^2 + k_3 x^3 + \cdots = V(x) + \sum_{j \neq i} \mu \left( \frac{M_i M_j}{M_i + M_j} \right) R_{ij}, \quad (15) $$

   $\mu = \frac{M_1 M_2}{M_1 + M_2}, \quad \hat{R} = \frac{R}{|R|}.$
Here $k_{eff}$ is effective spring constant, and $k_3$ the cubic parameter giving an asymmetry in the pair distribution function. The correlated Einstein model may be defined as a oscillation of a pair of atoms with masses $M_1$ and $M_2$ (e.g., absorber and back-scatterer) in a given system. Their oscillation is influenced by their neighbors given by the last term in the left-hand side of Eq. (15), where the sum $i$ is over absorber ($i = 1$) and back-scatterer ($i = 2$), and the sum $j$ is over all their near neighbors, excluding the absorber and back-scatterer themselves. The latter contributions are described by the term $V(x)$.

Using the Morse potential of Eq. (1) in the approximation for weak anharmonicity in the XAFS theory by the expansion

$$V(x) = D \left( e^{-2\alpha x} - 2e^{-\alpha x} \right) \cong D \left( -1 + \alpha^2 x^2 - \alpha^3 x^3 + \cdots \right),$$

(16)
to the effective potential of the system of Eq. (15) (ignoring the overall constant for convenience) we obtain

$$k_{eff} = D\alpha^2 \left( S - \frac{15}{2} \alpha a \right) = \mu \omega_E^2; \quad k_3 = \frac{5}{4} D\alpha^3; \quad \theta_E = \frac{\hbar \omega_E}{k_B},$$

(17)

where $x$ is the deviation of instantaneous bond length between the two atoms from equilibrium, $\alpha, D$ were defined above; $k_B$ is the Boltzmann constant; $\omega_E, \theta_E$ are the Einstein frequency and Einstein temperature; $a$ describes the asymmetry of the potential due to anharmonicity.

Using the definition [9] $y = x - a$ as the deviation from the equilibrium value of $x$ at temperature $T$ and quantum statistical theory [24] the MSRD is described by

$$\sigma^2 = \frac{1}{Z} \text{Tr} \left( \rho y^2 \right) = \frac{1}{Z} \sum_n e^{-n\hbar \omega_E} \langle n | y^2 | n \rangle = \frac{\hbar \omega_E (1 + z)}{2k_{eff} (1 - z)}, \quad z = e^{-\theta_E/T},$$

(18)

where we express $y$ in terms of anihilation and creation operators, $\hat{a}$ and $\hat{a}^+$, i. e.,

$$y = \kappa (\hat{a} + \hat{a}^+); \quad \kappa^2 = \frac{\hbar}{2\mu \omega_E}$$

(19)

and use harmonic oscillator state $|n\rangle$ with eigenvalue $E_n = n\hbar \omega_E$ (ignoring the zero point energy for convenience).

Therefore the expression for the MSRD is resulted as

$$\sigma^2(T) = \sigma_o^2 \frac{1 + z}{1 - z}, \quad \sigma_o^2 = \frac{\hbar \omega_E}{2SD\alpha^2},$$

(20)

where $\sigma_o^2$ is the zero-point contributions to $\sigma^2$.

In the derivation of the above expressions we have developed a structural parameter

$$S = 2 + \sum_{j=2}^N \left( \hat{R}_{0j} \cdot \hat{R}_{0j} \right)^2; \quad \hat{R} = \mathbf{R}/|\mathbf{R}|,$$

(21)
2. Equation of state

It is possible to calculate the equation of state from the energy $\Phi$. If it is assumed that the thermal part of the free energy can be adequately represented by the Debye model, then the Helmholtz free energy is given by [1]

$$
F = \Phi + 3Nk_B T \ln \left(1 - e^{-\theta_D/T}\right) - Nk_B TD \left(\frac{\theta_D}{T}\right), \tag{22}
$$

where $\theta_D$ is Debye temperature, the remaining parameters were defined above.

Using Eqs. (22, 23) we derive the expression for pressure $P$ leading to the equation of state as

$$
P = -\left(\frac{\partial F}{\partial V}\right)_T = \frac{1}{3ca^2} \frac{d\Phi}{da} + \frac{3\gamma_G RT}{V} D \left(\frac{\theta_D}{T}\right), \tag{24}
$$

where $\gamma_G$ is Grüneisen parameter, $V$ is the volume.

After some transformations the equation of state (24) is resulted as

$$
P = \frac{1}{3ca_0^2(1-x)^{2/3}} \left[ 2L/\beta^2 \sum_j M_j e^{-\alpha_0 M_j (1-x)^{1/3}} \right] - 2L/\beta \sum_j M_j e^{-2\alpha_0 M_j (1-x)^{1/3}} + \frac{3\gamma_G RT}{V_0(1-x)} D \left(\frac{\theta_D}{T}\right), \tag{25}
$$

where $x = \frac{V_0-V}{V_0}$, $V_0 = ca_0^3$, $R = Nk_B$, $N = 6.02 \times 10^{23}$. \(26\) Hence, the equation of state (25) contains the obtained Morse potential parameters.

IV. NUMERICAL RESULTS AND COMPARISON TO EXPERIMENT

Now we apply the above derived expressions to numerical calculations for some fcc, bcc and hcp crystals. Considering the distribution of atoms in the crystals and volume per atom we calculated the values of $c$ in Eq. (10) and structural parameter $S$ according to Eq. (21) for these crystal structures, the results are given in Table 1. Hence, for fcc Eq. (20) becomes Eq. (9) in Ref. [10].

Fig. 1. Morse potentials calculated by present procedure in comparison to experiment (dashed) for Cu (a) and for W (b)

Using the energy of sublimation, the compression and the lattice constants [13, 21, 22] we calculated the Morse potential parameters for Cu (fcc), W (bcc) and Zn (hcp). The results are presented in Table 2 in comparison to those of other theory [1] and of experiment [11, 12]. The accuracy of our results compared to experiment is about 2% for $D$; 1.6% for $\alpha$ of Cu; 0.2% for $D$, 3.8% for $\alpha$ of W and 0.3% for $\alpha$ of Zn. They also agree well with those for Cu and W of the other theory [1].

Comparison of our calculated Morse potential to experiment is illustrated in Fig. 1a for Cu and Fig. 1b for W. The temperature dependent MSRD calculated by using our above calculated Morse potential parameters are compared to the ones measured at HASYLAB, DESY (Germany) for Cu [17, 19] (Fig. 2a) and for Zn [20] (Fig. 2b) providing very good agreement.
The next application of our calculated Morse potential parameters is to the calculation of the equation of state for Zn. The values of $\theta_D$ and $D(\theta_D/T)$ were taken from [23]. The calculated results are shown in Fig. 3 in comparison to the experimental values [21] represented by an extrapolation procedure of the measured data. They show a good agreement between theoretical and experimental results, especially at low pressure.

V. CONCLUSIONS

A new procedure for calculation of Morse potential parameters for fcc, bcc and hcp crystals has been developed and the obtained results are applied to calculation of Debye-Waller factors in the XAFS theory and to the equation of state. The derived expressions have been programed for the computation of the considered physical quantities.

The calculated Debye-Waller factor and equation of state satisfy all standard conditions for the considered quantities such as Debye-Waller factors are linearly proportional to temperature at high temperature and contain zero-point contribution at low temperature.
Resonable agreement of our results with the respective experimental and other theory values show the efficiency and reliability of the present procedure in computation of the atomic interaction potential parameters as the Morse potential which are important for calculation and analysis of physical effects in XAFS technique and in solving the problems involving any type of atomic interaction in the fcc, bcc and hcp crystals.

ACKNOWLEDGMENTS

The authors thank Prof. R. R. Frahm and Dr. L. Tröger for providing the measured values of MSRD of Zn and Cu. This work is supported in part by the special research project of VNU-Hanoi QG. 03.02 and by the Basic Science Research Program No. 41.10.04.
